## ACKNOWLEDGEMENTS

The author wishes to express his deep sense of gratitude to Prof. O.P. Agnihotri, for his able guidance, tireless and continuous supervision and personal interest throughout the progress of this investigation without which the present work would not have been possible.

The author is also grateful to Prof. M.S. Sodha, Deputy Director of IITD, and Prof. S.S. Mathur of Centre of Energy Studies for the provision of special facilities for this work. The author is also thankful to Prof. B.B. Tripathi, for his kind help and encouragement.

It is with great pleasure the author acknowledges the help and co-operation of his colleagues Drs. A.K. Sharma, A. Raza, B.K. Gupta, S.S. Negi, J.V. Iyer, S.B. Gadgil, N. Tiwari, A. Raturi, T. Kumar and A. Bharadwaj for their help, co-operation and moral support during the progress of the work.

The author would be failing in his duty, if he does not express his appreciation for Mr. A.K. Maithani for his efficient and accurate typing and for Mr. Narendra Kumar who made excellent figures with great patience.

The author's thanks are also due to CSIR for the financial assistance rendered to him during the course of the research work.

## ABSTRACT

Selective surfaces are used in flat-plate collectors to convert solar energy into heat. They are characterized by their high absorptivity in the visible region of the solar spectrum (0.3 to 2.5 microns) and low emissivity in the thermal infrared region (2.5 to 25 microns), compared to a black body which is highly absorbing in the visible and also highly emitting in the infrared. Lead sulfide which has a direct band gap of 0.4 eV, when deposited on a highly reflecting metal like aluminium, satisfies the criterion<sup>o</sup> for a selective surface. Because it has a band gap of 0.4 eV, which lies in the transition region between visible and thermal radiations, it absorbs the visible radiations completely and transmits the infrared. Since PbS is transparent to infrared and the metal is highly reflecting, the net result is low emissivity. Even though the bulk PbS has a large refractive index of 4.7 which might result in low absorptance due to the reflections of the visible radiations, the PbS in the film form has a porous structure and the resultant refractive index becomes low and increases the absorptance.

In this thesis, two methods of preparation of PbS films have been described. In the first method, PbS has been prepared by spray pyrolysis technique. A solution of lead acetate and thiourea in water, was sprayed from a double nozzle sprayer, on to a hot substrate. The substrate temperature was monitored by a uniformly heated hot plate. Substrate temperature, spray rate, the mole concentrations of the initial solutions and the thickness of the film were optimized to get high solar absorptance and low thermal emittance. It has been found that a substrate temperature of 200°C with a spray rate of 5 ml/min gave a high absorptance of 0.93 and an emittance of 0.15 for an initial solution of 1L3T composition where 1L3T stands for 1 part lead acetate and 3 parts thiourea. The thickness was optimized to get destructive interference in the visible region of the spectrum.

In the second method, PbS was deposited by vacuum evaporation of PbS powder on metallic substrates like Al, galvanized iron, mild steel etc. The films were deposited at a lower rate (20 Å/sec) because a higher deposition rate gave sooty films and were non-adherent. Both absorptance and emittance increase with increase in thickness. Maximum selectivity  $\left(\frac{\alpha}{\epsilon}\right)$  obtained was 25 for a film thickness of 400 Å, but the absorptance

was only 0.8 for this thickness. Coatings with  $\alpha$  greater than 0.9 were used for further studies.

It was found that the emittance increases with temperature in sprayed as well as vacuum evaporated coatings. In the case of evaporated coatings, the increase in emittance with temperature was mainly due to the increase of emittance of the bare metal. Stagnation temperatures were measured for both sprayed and evaporated coatings. Sprayed coatings gave a stagnation temperature of  $120^{\circ}\text{C}$  and the evaporated coatings gave  $130.2^{\circ}\text{C}$ . The higher stagnation temperature in evaporated coatings is due to better selectivity. Electron micrographs have revealed that the evaporated coatings are more porous in nature than the sprayed coatings which results in the better absorptance of the evaporated coatings. A new technique is reported to measure the emittance of the coatings using Golay detector.

Accelerated life testings were done on both sprayed and evaporated coatings. The coatings ~~did~~ not deteriorate appreciably due to thermal cycling upto  $200^{\circ}\text{C}$  and started deteriorating if the upper temperature was further increased. The coatings were also stable if annealed below  $200^{\circ}\text{C}$ . Ultraviolet irradiations in air causes photo oxidation of  $\text{PbS}$  to  $\text{PbSO}_4$  and increases the

emittance of the coating because  $\text{PbSO}_4$  has an absorption band around 9 microns. In vacuum environment coatings were stable under UV irradiations. High percentage of relative humidity corrodes the substrate and increases the emittance.

$\text{PbS}$  was also tried as a junction material in heterojunctions for photovoltaic energy conversion of solar radiations. Since the lattice parameter can be varied in  $\text{Cd}_{1-x}\text{Zn}_x\text{S}$  by varying the composition, it is possible to match the lattice parameters and electron affinities of  $\text{n-Cd}_{1-x}\text{Zn}_x\text{S}$  and  $\text{p-PbS}$ , so that  $\text{CdZnS} - \text{PbS}$  cell gives better open circuit voltage. A voltage of 0.5V was obtained for a  $\text{CdZnS} - \text{PbS}$  cell compared to 0.39 V for a  $\text{CdS-PbS}$  cell for an illumination intensity of  $100 \text{ mW/cm}^2$ . The cell did not deteriorate in 4 months of time.

## CONTENTS

CHAPTER		PAGE NO.
I	INTRODUCTION	1
	1.1 Introduction	1
	1.2 Present Status of Solar Selective Surfaces	4
	1.3 Present Status of Lead Sulfide in Solar Energy Conversion	16
	1.4 Aim of the work	20
	1.5 Present Studies	21
II	BASIC CONCEPTS OF SELECTIVE SURFACES AND SOLAR CELLS	24
	2.1 Absorptance	24
	2.2 Emittance	26
	2.3 Tabor's concept of a selective surface	28
	2.4 Stagnation temperature	42
	2.5 Figure of merit	45
	2.6 Theory for a homogeneous coating	46
	2.7 Selective properties in porous PbS	57
	2.8 Hall effect	60
	2.9 Solar cell parameters	52

III	PREPARATION AND EXPERIMENTAL TECHNIQUES	65
3.1	Preparation of PbS films by spray pyrolysis technique	65
3.2	Preparation of PbS films by vacuum evaporation	67
3.3	Preparation of CdS and CdZnS films	69
3.4	Fabrication of Cd <sub>1-x</sub> Zn <sub>x</sub> S - PbS heterojunctions	70
3.5	Cleaning	71
3.6	Thickness measurements	72
3.7	Measurement of $\alpha$	75
3.8	Emissivity measurements	76
3.9	Thermal Cycling	81
3.10	Ultraviolet Studies	83
3.11	Humidity Testing	84
3.12	Aging test at elevated temperatures	84
3.13	Hall measurements	85
3.14	Scanning Electron Microscope Studies	88

IV	SELECTIVE PROPERTIES OF SPRAYED AND VACUUM EVAPORATED COATINGS	89
	4.1 Effect of substrate temperature on the selective properties of sprayed coatings	89
	4.2 Effect of mole concentration ratio on the selectivity	91
	4.3 Effect of thickness on the absorp- tance and emittance of the vacuum evaporated and sprayed coatings	100
	4.4 Effect of substrate on the emissivity of sprayed and vacuum evaporated PbS coatings	113
	4.5 Temperature variation of emittance	117
	4.6 Stagnation temperature	118
V	DURABILITY TESTS	128
	5.1 Effect of thermal cycling	128
	5.2 Effect of ultraviolet irradiations	135
	5.3 Effect of Humidity	141
	5.4 Effect of Elevated temperature	147
VI	ELECTRICAL AND PHOTOVOLTAIC PROPERTIES	155
	6.1 Electrical properties	155
	6.2 Photovoltaic properties	157

VII	SUMMARY AND CONCLUSIONS	166
7.1	Summary of results	166
7.2	Comparison of pbs selective coatings prepared by spray pyrolysis and vacuum evaporation	170
7.3	Suggestions for future work	171
